

HERBICIDE SITE-OF-ACTION AND MODE-OF-ACTION

The agriculture industry has now become burdened with herbicide resistance [HR] that is occurring in common problematic weeds. There is no doubt that this is one of the most profound and devastating problems the industry has faced in several decades, and dealing with it has now become one of the top if not the top concern among soybean producers. It cannot be ignored.

The popular and scientific press are filled with articles about this subject. Industry specialists are scrambling to provide weed management schemes that will address this issue and that will delay or prevent the occurrence of HR weeds where they are not already present.

One of the subjects that is prevalent in the discourse surrounding the subject is how the various herbicides work to control weeds. This leads to use of the terms “site-of-action [SOA]” and “mode-of-action [MOA]”. These two terms are often used interchangeably, but they in fact mean two different things. The following linked articles provide information that helps to differentiate between the two terms.

“[What’s the difference between herbicide mode of action and site of action](#)” by Dr. Gared Shaffer of South Dakota State University provides the following information.

- “All herbicide interactions with the plant, from application to final effect, are considered the **mode of action**. The MOA involves absorption into the plant, translocation or movement in the plant, metabolism of the herbicide, and the physiological plant response.” In other words, the mechanism by which a herbicide kills a plant is known as its **mode of action**.
- “Herbicide **site of action** is the specific process in plants that the herbicide disrupts to interfere with plant growth and development. The SOA is the most important aspect of herbicides when dealing with prevention and control of HR weeds.”

According to the content of an article titled “Herbicide Site of Action, Mode of Action Differences” that appeared in Ag Professional magazine, “The site of

action is the location within the plant where the herbicide impacts the development process. The mode of action is the name for the process the herbicide uses to control the weed. So site of action is ‘where’ and mode of action is ‘how’”. According to Dr. Bryan Young in the same article, “Typically the target is an enzyme used in carrying out a process like amino acid production or photosynthesis. The herbicide targets the enzyme and stops the process”.

Dr. Joe Armstrong of Oklahoma State University authored an article titled “[Understanding Herbicide Mode of Action](#)”, where he states “The mode of action is the way in which the herbicide controls susceptible plants. It usually describes the biological process or enzyme in the plant that the herbicide interrupts, affecting normal plant growth and development. In other cases, the mode of action may be a general description of the injury symptoms seen on susceptible plants. Some herbicide modes of action comprise several chemical families that vary slightly in their chemical composition, but control susceptible plants in the same way and cause similar injury symptoms.” He further states that “herbicides can also be classified by their ‘site of action’, or the specific biochemical site that is affected by the herbicide. The site of action is a more precise description of the herbicide’s activity.”

“[Herbicide Sites of Action](#)” by Dr. Bob Hartzler of Iowa State University presents the following.

- Herbicides kill plants by binding to a specific protein and inhibiting that protein’s function.
- The protein is referred to as the herbicide’s **site of action**.

An example of how site of action and mode of action differ in their meaning is provided in the article titled “[Herbicide Site of Action and Injury Symptoms](#)” by Iowa State Univ. Extension.

- “A triazine herbicide [e.g. atrazine, metribuzin] interferes with photosynthesis by binding to the D1 protein involved in photosynthetic electron transfer. Thus, the site of action for triazines is the D1 protein, whereas the mode of action is disruption of photosynthesis.”

INFORMATION**

The Weed Science Society of America [WSSA] has devised a number system that can be used to classify individual herbicides according to their MOA and SOA. Examples from Dr. Shaffer’s article are shown in the below table. This WSSA numbering system 1) allows users to evaluate a herbicide program based on the SOA, with SOA diversity being an important component of a weed control program designed to prevent or delay HR, and 2) can be used to blend the “site of action” and “mode of action” information into one piece of knowledge that can be used to select a weed management program that includes diverse herbicides.

Click [here](#) for a detailed presentation on how to use MOA to select herbicides.

Herbicide MOA	Herbicide SOA–WSSA number	Herbicide Examples
Lipid synthesis inhibitors	ACC-ase inhibitors–1	Poast, Select, Fusilade DX
Amino acid synthesis inhibitors	ALS inhibitors–2	Classic, FirstRate, Pursuit
	EPSP synthase inhibitor–9	Roundup
Nitrogen metabolism inhibitors	Glutamine synthetase inhibitor–10	Liberty, Cheetah
Pigment inhibitors	HPPD inhibitors–27	Callisto
Cell membrane disruptors	PPO inhibitors–14	Valor, Sharpen, Blazer
	Photosystem I inhibition–22	Gramoxone
