SOYBEAN VARIETIES' DISEASE RATINGS—2020

Dr. Tom Allen, Extension Plant Pathologist at DREC-Stoneville, has posted ratings for various diseases that affect soybean varieties that were grown in the 2020 Mississippi Soybean Official Variety Trials (OVT) at Brooksville, Clarksdale, Longwood, Olive Branch, Raymond, Stoneville, Tippo, and Verona. Varieties were rated for indicated foliar diseases at the indicated locations in the appended tables.

Varieties were rated when plants were between R6 and R6.5. Ratings are based on each variety's reaction to natural infestations of each disease at each location; i.e., plants were not inoculated with disease pathogens. Thus, the ratings do not presume to indicate a variety's response to a known yield-reducing level of the pathogen. Rather, the ratings are to be used as an indicator of each variety's reaction to the level of the pathogen present at each location in 2020. Cercospora blight, Septoria brown spot, southern blight, and target spot were the most common diseases that occurred at each location.

Evaluations for the presence of diseases were conducted using a 0 to 9 scale where 0 = no disease and 9 = intense disease symptoms.

For frogeye leaf spot (FLS), amount of affected leaf surface area was estimated. 2020 was not a good year for FLS evaluations. However, the FLS data from Tippo appear to be valuable when considering varietal reaction to this disease.

Cercospora leaf blight (CLB) ratings were based on the presence of the disease on leaves (0 to 5), petioles (6), and pods and stems (7 to 9). This was based on disease intensity as determined by coloration of plant material (leaves with distinct purple coloration, and petioles, pods, and main stems with purple to near black coloration).

Septoria brown spot (SBS) and target spot (TS) were rated based on the presence of the disease within the plant canopy, where 0 to 3 indicated presence in the lower canopy, 4 to 5 indicated presence in the middle canopy, 6 to 8 indicated presence in the upper canopy,

and 9 indicated extensive defoliation throughout the entire plant canopy and the disease present in the uppermost canopy.

Southern blight (SB) ratings were based on presence of disease on plants in an entire plot where 0 = no disease, 5 = plants in approximately half the plot exhibited symptoms, and 9 = severe infestation characterized by dead plants. In numerous cases, either white fungal growth or sclerotia (signs associated with southern blight) were noted at the base of infected plants.

Green stem ratings were made using a 0-100% scale and are based on the percentage of plants in the entire plot that had green stems and green leaf material, but mature pods.

Note: Locations with a non-irrigated trial are designated with an (N) following the location name.

Statistics

MSE (Mean Squared Error). The MSE of an estimator measures the average of error squares—i.e. the average squared difference between the estimated values and true value. It is a risk function, corresponding to the expected value of the squared error loss. The MSE assesses the quality of an estimator (the ratings shown here are estimators of how a variety will tolerate a disease). In other words, it measures the quality of the estimate of the disease incidence (ratings) on the varieties in the accompanying tables. It is always positive and values closer to zero are better—i.e., an MSE of zero means the estimate predicts disease infection potential with perfect accuracy. Of course, this is typically not possible, especially where the disease levels assessed in these environments are based on their natural occurrence, which may have been non-existent or very low.

Probability level (*p* value). The smaller the probability level, the more stringent the statistical test.

WWW.MSSOY.ORG ⇒ MSPB WEBSITE WITH
UP-TO-DATE SOYBEAN PRODUCTION
INFORMATION

CV (coefficient of variation) and/or R² (coefficient of determination). These values are a measure of the relative precision of a given trial and can be used to compare the relative precision of different trials. The CV is generally considered to be an estimate of the amount of unexplained variation in a given trial or test, while the R² is a measure of the amount of variation that is explained or accounted for in a given test. A CV below 10% (10% unexplained variation in a trial) is desired, while an R² above 0.90 (90% of the variation in a trial has been accounted for) is desired.

Ratings

Data obtained from Mississippi soybean OVT tests that were rated for disease infection are presented in the following attached tables.

Tables 1-7. Cercospora leaf blight (CLB) severity ratings for soybean varieties, Miss. OVT, 2020.

Tables 8-14. Frogeye leaf spot (FLS) severity ratings for soybean varieties, Miss. OVT, 2020.

Tables 15-21. Septoria brown spot (SBS) severity ratings for soybean varieties, Miss. OVT, 2020.

Tables 22-28. Southern blight (SB) severity ratings for soybean varieties, Miss. OVT, 2020.

Tables 29-35. Target spot (TS) severity ratings for soybean varieties, Miss. OVT, 2020.

Tables 36-42. Green stem ratings for soybean varieties, Miss. OVT, 2020.
