**SOYBEAN VARIETIES' FOLIAR DISEASE RATINGS–2018**

Dr. Tom Allen, Extension Plant Pathologist at DREC-Stoneville, has posted ratings for various diseases that affect soybean varieties that were grown in the 2018 Mississippi Soybean Official Variety Trials (OVT) at Brooksville, Clarksdale, Longwood, Olive Branch, Raymond, Stoneville, Tippo, and Verona. Varieties were rated for indicated foliar diseases at the indicated locations in the appended tables. Varieties were rated when plants were between R6 and R6.5. Ratings are based on each variety's reaction to natural infestations of each disease at each location; i.e., plants were not inoculated with disease pathogens. Thus, the ratings do not presume to indicate a variety's response to a known yield-reducing level of the pathogen. Rather, the ratings are to be used as an indicator of each variety's reaction to the level of the pathogen present at each location in 2018.

Frogeye leaf spot (FLS) ratings were not made at any location because of a lack of major presence. For Cercospora leaf blight (CLB), ratings were based on the presence of the disease on leaves (0 to 5), petioles (6), and pods and stems (7 to 9), and this was based on disease intensity as determined by coloration of plant material (leaves with distinct purple coloration, and petioles, pods, and main stems with purple to near black coloration). Septoria brown spot (SBS) and target spot (TS) were rated based on the presence of the disease within the plant canopy, where 0 to 3 indicated presence in the lower canopy, 4 to 5 indicated presence in the middle canopy, 6 to 8 indicated presence in the upper canopy, and 9 indicated extensive defoliation throughout the entire plant canopy and the disease present in the uppermost canopy.

**SOYBEAN VARIETIES' STEM CANKER RATINGS–2018**

All entries in the 2018 Mississippi OVT were evaluated for their reaction to inoculation with the stem canker fungus by Dr. Tom Allen, Extension Plant Pathologist at the MSU-DREC. Additional varieties (n=10) that were not entered in the Miss. OVT were also evaluated.

Trials consisted of four replicates of single rows of each cultivar planted in 10-foot-long plots. Within each row, 10 plants were inoculated with a single toothpick that contained the fungus that causes stem canker (four isolates of the fungus were used for a fungal cocktail on toothpicks). Plants were inoculated approximately 8 weeks post-planting. Evaluations of stem canker severity were conducted between R6 and R6.5 by observing the stem of each inoculated plant for the presence of a canker. Ratings of each variety were made using a modified 0-9 scale (see each table's footnote for rating scale).

Information within each table contains the analyzed stem canker rating as an average of all inoculated plants in the four replicates. In addition, each cultivar includes a stem canker susceptibility designation; i.e., R = resistant, MR = moderately resistant, MS = moderately susceptible, and S = susceptible.

In fields where stem canker has been documented, soybean cultivars that are resistant to stem canker have been observed. In addition, keep in mind that observations of stem canker tend to be more obvious when the environment is conducive for disease development. Therefore, over time, and in years when the environment may not be conducive for the development of stem canker, it is possible that stem canker designations could change among years. Moreover, as additional fungal isolates are added to the collection, it is possible that the rating as well as the designation for any cultivar can change accordingly.

Please note: The statistical analysis used on these stem canker data—a rank transformation prior to the means

analysis—may make some values appear skewed. The letter groupings listed after values are for the rank transformed values, but the non-transformed data are presented to show the true mean of the scores assigned in the field.

### Statistics

**LSD (least significant difference).** These values are used as a statistical tool to determine significant differences among variety ratings. The average ratings of any two varieties being compared must differ by more than the LSD value to be considered different in a particular test.

Put another way, the LSD is the smallest difference between ratings of two varieties that can be attributed to an actual difference in the varieties' disease susceptibility in a particular trial. Thus, a difference in the ratings of two varieties that exceeds the LSD is attributable to a difference in the disease susceptibility of the two varieties. Even though the average ratings of two varieties may be numerically different, the two disease ratings are not considered significantly different if that difference does not exceed the test LSD.

**Probability level (*p* value).** A disease rating difference between two varieties that exceeds the LSD value will be expected to do so 9 times out of 10 at the 10% (.10) level of probability, 19 times out of 20 at the 5% (.05) level, 99 times out of 100 at the 1% (.01) level, etc. The smaller the probability level, the more stringent the statistical test.

**CV (coefficient of variation) and/or R<sup>2</sup> (coefficient of determination).** These values are a measure of the relative precision of a given trial and can be used to compare the relative precision of different trials. The CV is generally considered to be an estimate of the amount of unexplained variation in a given trial or test, while the R<sup>2</sup> is a measure of the amount of variation that is explained or accounted for in a given test. A CV below 10% (10% unexplained variation in a trial) is desired, while an R<sup>2</sup> above 0.90 (90% of the variation in a trial has been accounted for) is desired.

Data from Mississippi soybean OVT tests that were rated for disease infection are presented in the following tables (Tables 1-6 are intentionally missing).

Tables 7-9 Reaction of MG IV conventional soybean varieties to indicated diseases, OVT, 2018.

Tables 10-12 Reaction of MG IV early soybean varieties to indicated diseases, OVT, 2018.

<sup>1</sup>Stem Canker Reaction-Eight plants per plot were inoculated with infested toothpicks. Ratings were given by individual plant reaction using a modified 0-9 scale based on lesion severity and are presented as the average for the eight plants. Where a lesion did not appear, a rating of 0 (Resistant) was assessed. Ratings were assessed based on the presence of a lesion whereby a reaction that produced a visible lesion that did not expand up the length of the stem was assessed as a 1. Dead plants with lesions that extended up most of the plant's length received a score of 9.

<sup>2</sup>Means followed by the same letter(s) within a column are not significantly different according to Fisher's Protected LSD ( $P=0.05$ ).

<sup>3</sup>By using the Mean Disease Rating, a standardized designation system is as follows: 1 = Resistant, 3 = Moderately Resistant, 5 = Moderately Susceptible and 7 = Susceptible.

<sup>1</sup>Stem Canker Reaction-Eight plants per plot were inoculated with infested toothpicks. Ratings were given by individual plant reaction using a modified 0-9 scale based on lesion severity and are presented as the average for the eight plants. Where a lesion did not appear, a rating of 0 (Resistant) was assessed. Ratings were assessed based on the presence of a lesion whereby a reaction that produced a visible lesion that did not expand up the length of the stem was assessed as a 1. Dead plants with lesions that extended up most of the plant's length received a score of 9.

<sup>2</sup>Means followed by the same letter(s) within a column are not significantly different according to Fisher's Protected LSD (*P*=0.05).

<sup>3</sup>By using the Mean Disease Rating, a standardized designation system is as follows: 1 = Resistant, 3 = Moderately Resistant, 5 = Moderately Susceptible and 7 = Susceptible.
